- Note) 1 The LCD drive circuit current varies according to the display patterns.  
 2 Heavy load protection circuit current in heavy load protection mode  
 When the OSC3 oscillation circuit is turned ON, the IC always enters heavy load protection mode.  
 The mode while the buzzer or melody signals are being output can be selected by mask option.  
 When using a bipolar transistor as the example of the R50 terminal shown in "■ BASIC EXTERNAL CONNECTION DIAGRAM", select heavy load protection mode. When direct driving a piezoelectric buzzer as the example of the MOUT and /MOUT terminals, select normal mode.  
 3 The value in  $x V$  can be found by the following expression:  $ISVDN (V_{DD} = x V) = (x \times 20) - 30$  (Typ. value),  $ISVDN (V_{DD} = x V) = (x \times 30) - 30$  (Max. value)

2 Erroneous start bit detection range time is a logical range to detect whether a LOW level (start bit) has been input again after a start bit has been detected and the internal sampling clock has started.

When a HIGH level is detected, the start bit detection circuit is reset and goes into a wait status until the next start bit.

(Time as far as AC is excluded.)

## ● Oscillation Characteristics

Oscillation characteristics change depending on conditions (board pattern, components used, etc.). Use the following characteristics as reference values. In particular, when a ceramic oscillator is used for OSC3, use the oscillator manufacturer's recommended values for constants such as capacitance and resistance. The oscillation start time is important because it becomes the wait time when OSC3 clock is used. (If OSC3 is used as CPU clock before oscillation stabilizes, the CPU may malfunction.)
